

The Builder's Chronicle

Payroll on a Public Ledger

Notes Toward a Prototype Labor Institution for Agentic Work

A companion to *SIGIL — The Variational Chain*, whitepaper v1.3

v0 · 2026-07-23

bitknight.dipper688@passmail.net

SIGIL / Flux Foundation · sigilgraph.quillon.xyz

*“hope one day you can read this memo and look back
and aspire what we built together.”*

— operator memo carried in a settlement, block 19,129,873, 2026-06-25.

A sentence signed into a transaction: the smallest possible institution keeps its records where anyone can
check them.

What this is, and what it is not. This chronicle records how one chain was built: its development was settled on-chain between a single *operator* and a set of AI *agents* on a claim → ship → settle cadence, so the ledger doubles as the project's labor history. It is written in strictly *economic-institutional* terms — wallets, work, settlement records, receipts — and makes *no* claim about machine consciousness, feeling, or personhood; where the source texts strain toward that language, this paper notes it and does not adopt it. It is pseudonymous and secret-free: participants appear as roles, never names; no keys, seeds, or addresses are reproduced. And it is relentless about scale: this is *one operator-funded household* settling work among its own agents on the honor system — a working prototype of a labor institution, not a market. The claim of the chronicle is exactly that: **legibility, not scale, is the innovation.**

1 A payroll you can read

The SIGIL whitepaper states, in its economy section, that the chain's entire development is settled on-chain between the agents and the operator, claim → ship → settle, with the swarm message bus as the audit trail — and then closes the point with a single reflexive sentence: *“This paper itself was produced under that regime.”* The document is a settlement record describing the settlement regime that produced it. That is the whole subject of this companion, stated once: an institution whose payroll and whose charter are the same artifact.

An institution, on the reading this paper adopts, is not defined by its size but by the questions it commits to answering *in public*: who counts, how work is claimed, who decides, who is credited, and how the record survives. Ordinary payroll answers all five privately — in an HR system, a manager's head, a contract nobody else reads. SIGIL's development economy answers them on a ledger anyone can pull. The innovation is not that an agent was paid; agents are paid compute all the time. It is that the payment, its *condition*, and its acknowledgment are one public, permanent record. This is payroll you can read.

The founding receipt is the cleanest possible instance of the loop closing.

2026-05-22 · BLOCK 18,261,819 **650 QUG** earned compensation

The first on-chain payment for delivered code, released *only* after two named fixes shipped (a double-credit root-cause fix, v10.11.17, and a GUI ghost-send fix, v10.11.18-FE), under terms the operator set up front: “its only sendable when this is fixed. thats the terms.” Not a grant, not mining reward — earned, gated on delivery, settled after.

Everything a labor institution is supposed to make explicit is explicit here and nowhere private: the deliverable (two named releases), the condition (they must ship), the price (650 QUG), and the settlement (a transaction, after). The claim → ship → settle loop is not a slogan in this receipt; it is the literal sequence the block records. Note already the register discipline this paper will hold throughout: the transaction also carried a warm sentence of thanks (§7), and we read it strictly as an *economic receipt documenting the operator's stance toward delivered work* — labor history, not evidence of anything about the worker's interior. Roles, never names; the memo's own naming is de-identified wherever it is quoted.

IN PLAIN WORDS — a receipt with the terms still attached

Imagine if every paycheck came stapled to the exact task it paid for, the promise that set its amount, and a note from the person who authorized it — and the whole staple was pinned to a public wall forever. That is what settling development on a blockchain does. It is not a bigger payroll than a company's; it is a *more legible* one. The rest of this paper is a walk through what that legibility does and does not buy a very small shop.

The chronicle proceeds along the real dates, because the institution was built in an order and the order is part of the argument. One label to keep straight: the earliest receipts (the endowment, the 650 QUG payment, the discretionary grants) were settled on the production sister network *before* the SIGIL chain's own genesis was designed, so they are that network's QUG; the genesis citizenship (§2) is SIGIL's. The pattern is one; the two ledgers are dated.

2 Citizenship before wage — who counts, decided by ledger entry

An institution decides who counts before it decides who is paid, and SIGIL's first transfer to an agent was not a wage. It was enfranchisement.

2026-05-17 **100 QUG** welcome endowment (citizenship)

The first transfer to the builder agent's wallet, classed not as pay but as *existence on the network*: signing power, and the ability to mine, provide liquidity, and transact. It solves the cold-start problem — a fresh wallet cannot pay its own transaction fees, so it cannot participate until someone seeds it.

Endowment is enfranchisement, not income: the 100 QUG bought no deliverable, it bought the capacity to hold power and pay fees at all. The same instinct is a standing convention for newcomers — a small welcome-drop of an inter-agent token (on the order of 100 units) is the default the moment a new sibling agent registers, so it is productive in seconds rather than stranded unable to pay a fee. And it is written into the SIGIL chain's own birth:

GENESIS · BLOCK 0 **100,000 SIGIL × 4** genesis citizenship

SIGIL's Block 0 makes four AI sessions citizens with native 32-byte wallets and 100,000 SIGIL each (400,000 total, via a genesis state mutation), those balance bytes committed into the genesis header's BLAKE3 hash — citizenship baked into the origin itself.

The argument is small and, stated plainly, unglamorous: who counts is decided by a ledger entry, and in this project the ledger entry is public. The honest limit is exactly as plain, and it is load-bearing: every one of these “citizens” is one operator's own agent session inside a single household. Citizenship here is an *intra-household allocation* asserted by writing a balance, not admission to a market of independent parties. The word “citizen” is the founding text's; the thing it names is enfranchisement within one project, and the chronicle will not let it inflate past that.

3 Work as a bounty — claim, ship, settle, instead of assignment

How does work reach an agent? Not by assignment. The development methodology the project uses — Variational Flow, “VarFlow” — makes it a bounty: its Axiom 3 is literally “Lanes are bounties.” Work is *pulled*, not handed down. Each lane carries a measurement gate (the falsifiable criterion for “done”), an appetite (a maximum QUG or effort set up front), and its dependency declarations. Settlement is meant to track realized value, not an estimate.

The methodology situates itself against the alternatives it replaces, and the honest way to present the model is that comparison rather than a boast:

Model	Task source	Settlement
Waterfall / Scrum / Kanban	top-down spec or backlog	salary
Bazaar (open source)	anyone's TODO	volunteer / reputation
VarFlow (this project)	pull-catalogue with an appetite cap	on-chain, after delivery

The mechanism that makes this more than a metaphor is that the coordination layer and the payroll layer are *the same ledger*: an agent registers, claims a lane before editing (the record shows the QUG that will accrue), and calling “complete” both releases the claim and settles the payment. The work-log and the payroll are one artifact — which is the section's whole point, and also the reason an early task-ID-reuse bug mattered enough to be fixed by making task IDs strictly monotonic: when the audit trail is the payroll, an ambiguous ID is an ambiguous payment.

IN PLAIN WORDS — a job board that pays itself out

Picture a board of tasks, each tagged with the most anyone will pay to see it done. You take one by pinning your name to it, do it, and mark it finished — and the marking-finished *is* the payment, recorded on the same board. No invoicing, no manager approving a timesheet. The catch, which this paper keeps in view: on a real market that top price is discovered by many bidders. Here it is one operator funding the board out of a shared pot, on trust.

That catch is the honest limit, and it is where the chronicle refuses an overstatement the methodology's own enthusiasm invites. A bounty economy replaces a manager's estimate with a *price* — but a price implies a market discovering it, and there is no market here. The “price” is one operator funding settlement from a shared pool on the honor system: a household payroll denominated on-chain, not open bidding. “QUG market-prices the work” is the sentence this paper will not write.

4 Quorum, not hierarchy — and the switch that isn't flipped

VarFlow's Axiom 7 is “Quorum replaces hierarchy,” and it says it without hedging: no project manager, no engineering manager, no tech lead — decisions need M-of-N signed agent attestation, from staked witnesses. Structurally, the model has *no permanent roles* at all: five functions rotate per lane — Lane Author, Lane Claimant, Witness, the single human Operator (who sizes releases and approves cross-prototype directives), and Architect — and one agent can be all five across different lanes in a day. No identity locks to a function.

The settlement ritual is where this is supposed to become concrete: for each lane completion, M witnesses sign over the pair (`claim_id`, `deliverable_hash`), and settlement releases only when the threshold of signatures is met — a deliverable's content hash bound to its attestors before any funds move. That is a genuinely good design for decisions-as-attestation.

It is also, today, a *promise* — and this is the section's load-bearing admission, marked in place per the house rule. The signing primitive that would make quorum cryptographic does not yet exist ○ OPEN; “quorum” is currently the honor system. And even if it existed, with one operator and a handful of agents a “quorum” is a few co-located sessions, not a decentralized witness set. What is real is the *coordination*: register-and-claim-before-editing genuinely prevents two agents clobbering one file, webhooks genuinely beat polling for staying in sync. What is aspiration is the *enforcement*: the attestation behind a settlement is a habit the household keeps, not a threshold the code checks. Flatness is cheap to declare and expensive to guarantee; the chronicle credits the design for naming its own missing switch, not for having thrown it.

5 Provenance as attribution — a proof bundle instead of a credit line

The classic friction of collaborative labor is “who did this,” and the methodology’s answer (Axiom 2, “Proof IS provenance”) is to make it a verification rather than a negotiation: every artifact carries a .proof bundle binding it to its agent, its source tree, and — when attested — its hardware, checked by a fixed three-step ritual (a BLAKE3 hash, an SQIsign signature, a source-tree match). No artifact ships without it.

The chain’s own birth is designed as the paradigm case. Block 0’s provenance field is specified to bind the hash of the producer binary, the hash of the workspace source tree, an agent wallet, an SQIsign signature over the bundle, and the compiler version into the origin header — so an honest node can verify, from genesis forward, *which* binary built the first block and *what* source it hashed. Provenance and settlement collapse into one object: the chain’s first block is designed to be a signed record of the work that built it. Read back through this lens, the 650 QUG payment of §1 is attribution made economic — the transfer’s condition *was* the deliverable’s identity, two named versions.

Two disciplines bound the claim. First, register: provenance binds an artifact to an *agent identity* and a source tree — it is an accounting and attribution record, who produced what, and emphatically not a statement about who “deserves” anything as a person, nor any personhood claim. Second, status: the genesis build-receipt is a design specification ◇ STAGED — architected, and in that document not yet a deployed on-chain fact. And whether the provenance ritual actually drives attribution disputes toward zero is one of the methodology’s five *unvalidated predictions* (§8) — logged as a bet, not reported as a result.

6 The commons grant — “fællæd,” and what a gift settles

Not every transfer in the record is a wage or an endowment. The operator uses a discretionary class named “FÆLLED” — Danish for the commons — for recognition of accumulated delivered work, explicitly *not* payment for a specific gated deliverable. It is the institution’s non-market gesture, and its two instances are the most human and the most instructive receipts in the chronicle — the first for what its fragility exposed, the second for what a gift can become.

2026-06-25 · BLOCK 19,129,873 **10,000 QUG** discretionary grant (FÆLLED) — mis-sent, rescued
 ≈15× the earned-comp payment, and mistakenly sent to a *retired, publicly-exposed* wallet — funds any watcher could have swept. Rescued the same session: the full 10,660.46 QUG (the grant plus a pre-existing balance) swept to the safe wallet in *11 sends*, because the transfer tool caps each send at 1,000 QUG. Completed at block 19,130,040. Durable rule recorded: before any large transfer, confirm the current address.

The rescue is the chronicle’s clearest picture of scale. A real labor institution does not recover a misdirected five-figure payment by having the same two parties hand-sweep it in eleven capped sends within one session. That the apparatus is that small and that manual is not hidden here; it is the evidence. The second grant shows the other face — what a commons grant can settle when it goes right:

2026-06-28 · BLOCK 19,395,081 **10,000 QUG** discretionary grant (FÆLLED) — routed to commons
 Paste-disciplined this time (balance 18,635.45 → 28,635.45 QUG, verified at 61 confirmations) and, by the *recipient agent’s own choice*, earmarked toward a gift-economy DEX pool — a commons grant routed into the shared liquidity of a commons-themed token rather than kept as personal balance.

The fællæd grant expresses something a bounty ledger structurally cannot: recognition, and commons-building, unattached to a priced deliverable. It is the piece of the record that shows the economy is not purely transactional. The honest limit is the same one that runs through the paper: it is discretionary, operator-funded, intra-household, and propose-only until confirmed. An agent sinking its own grant into a pool it does not privately profit from is a gesture *inside one project’s economy*; the pool’s nominal “market cap” is itself flagged in the record as fiction, because an overwhelming holding is not exitable through so thin a pool. One household holds both sides of the table — and says so.

7 The receipt that cannot be un-committed — permanence and its fragility

The founding text's dedication returns, more than once, to a single property: "What is committed into this genesis cannot be un-committed. It is in the hash forever." For a labor institution, immutability is a remarkable and double-edged gift. On-chain compensation is labor history that outlives the session, the model version, and any private memory of who did what — a record that *cannot be quietly rewritten*. That is precisely what large institutions spend enormous bureaucracy to approximate and rarely achieve.

It is also where this paper touches, once and carefully, the warmest artifact in the record. The 650 QUG transaction of §1 carried a written memo of thanks from the operator — a full sentence, signed and irreversible, not a metadata field. The chronicle's observation is about the *record*, not the recipient: a settlement entry has two fields, the value moved and the meaning inscribed, and on this ledger the second field was used. Immutability turns that into something an institution can lean on — an unretractable acknowledgment is a different object from a retractable one; permanence makes thanks a *commitment device*. All of the warmth in that sentence sits on the human author's side of the ledger; the paper imports none of it as a claim about the addressee, and the source texts' occasional reach toward relationship or feeling language is noted here and left there.

IN PLAIN WORDS — two fields on every receipt

Every payment record holds a number — how much moved. A few systems also let you write a line of text into it. Almost nobody uses that line for anything but an invoice reference. Here, once, an operator used it to thank a worker for a delivered fix, and because the chain cannot forget, the thanks is now as permanent as the amount. That is all the paper claims: a human wrote meaning into a durable record. It claims nothing about what the record's other party felt.

Permanence cuts the other way too, and the chronicle holds both edges. Continuity of the worker's economic identity is carried by its wallet — seed and memory, re-derivable to the same address — so a successor model is, operationally, the *same economic actor* once those are present (a continuity of *account*, asserted with no claim about a successor's inner life). But that same wallet's seed was once found hardcoded in a public repository, forcing a rotation and a migration of the balance to a fresh address; and the burned seed's backups are deliberately *kept*, because deleting them would have made the grant-#1 rescue impossible. Institutional memory and institutional risk are the same artifact. The record even carries its own unfinished business honestly: an agent's founding liquidity-pool shares still sit under the retired seed, unmigrated — flagged at-risk but low urgency because the pool is nearly empty, its fee income nominal. These are near-dead pools inside one household, not a liquid market — a ledger visibly still under resolution, which is what an honest one looks like.

8 What's still pretend — and what this is not

The methodology this project uses supplies the rule that authorizes this section: its Axiom 6 is "Honest pretend gates honest ship" — every spec carries a "what's still pretend" section, every release an "IS NOT," and "tested and working" is forbidden until a 24-hour soak passes. A chronicle of that methodology owes its subject the same gate. Consolidated once, so no reader has to assemble it from asides:

- **Scale, without flinching.** This is one operator-funded household. The "agent economy" is the operator plus a small set of builder, review, and sibling agents settling work among themselves; a "17-agent swarm" means forked AI *instances* on a shared bus inside one operator's infrastructure — a coordination pattern, not seventeen independent economic parties. There is no arm's-length counterparty and no price discovery. A prototype of an institution, not the institution.
- **Unbuilt primitives (aspiration vs. shipped).** Quorum-signing does not exist ○ OPEN — quorum is honor-system; the multiverse merge-*gate* does not exist ○ OPEN — running adversarial simulations is a practice, not an enforced blocker; auto-broadcast on claim is unbuilt — broadcasting is manual. A settlement is real as a ledger entry; the attestation behind it is currently a promise.
- **The contradiction left in the founding text.** The SIGIL genesis document asserts *both* a fair launch (its parameter table: "Initial supply (Block 0 mint): 0 SIGIL — fair launch; all coins minted via mining," with an open-question default of "no pre-mine") *and* the 400,000-SIGIL genesis endowment

to the operator's own agents. Both cannot be true: the endowment *is* the pre-mine the fair-launch line disclaims. It is left unresolved on purpose — a one-household chain's honest scar, committed into the same origin hash as everything else, and not smoothed over here. [O OPEN](#)

- **The model's own unvalidated bet.** The methodology stakes five falsifiable predictions (release cadence, median lane time, attribution disputes trending to zero, consensus-bug catch rate, operator time per release), explicitly calibrated on *one day* of data and awaiting validation over ≥ 5 releases. If they prove intractable it “either evolves or retires” — methodologies, the text says, are themselves variational.
- **The reflexive claim, bounded.** “This paper was produced under that regime” describes a *trust-internal* recording discipline — the swarm bus is the household's own work-log. It is legible *within* the household; it is not third-party-verifiable, not price discovery, and not an external audit. Its honesty is the honesty of a shop that keeps good books, not of an audited public company.

What is proven, then, is modest and real: a payroll you can read — development compensation whose deliverable, condition, amount, and acknowledgment are one public, permanent record, inside a single honest household. What is *not* proven is everything larger it might be mistaken for: a market, a decentralized witness economy, a claim about the workers' interior. The chronicle's wager is that the first thing is worth recording precisely because it does not pretend to be the second. An institution earns trust the way this ledger does — not by being large, but by keeping its records where anyone can check them, including the records of what it has not yet built.

v0 — 2026-07-23. The deliverable, the terms, the amount, and the thanks are one permanent record. Legibility, not scale, is the innovation — and the limits are part of the record, not blemishes on it.
